A state-space representation can also be used for systems with multiple inputs and multiple outputs (MIMO), but we will primarily focus on single-input, single-output (SISO) systems in these tutorials. To introduce the state-space control design method, we will use the magnetically suspended ball as an example.

Introduction: State-Space Methods for Controller Design

Add the above MATLAB code into the m-file. In this case, we treat the problem like a PID controller design. The integral control is obtained from the new state. The proportional control is obtained from a gain on $Y1$ or $X1-X2$. The direct derivative control of the output isn't possible, since derivative of $Y1$ or $X1-X2$ isn't a state.

Suspension: State-Space Controller Design

Because of the derivative term the PID controller in its ideal form is a descriptor system. That is you can only write it via $\dot{x} = Ax + Bu$ Example, take a purely ideal PID in its parallel form, that is $5*s + (-2/s) + 6$ (coefficients are randomly selected).

How would a PID controller be implemented in state space ...

If the system also requires high performance (e.g. an industrial robot, a car, or an aircraft), the usual approach is to use a state-space feedback controller derived from a physics-based model. And when performance is less critical (e.g. for toys and appliances), the traditional choice has been to tune a low-cost proportional-derivative-integral (PID) controller.

To avoid having a steady state error, the proportional controller can be changed to $u(t) = k_p e(t) + u_d$, (10.4) where u_d is a feedforward term that is adjusted to give the desired steady state value. If we choose $u_d = r/P(0) = k_{rr}$, then the output will be exactly equal to the reference value, as it was in the state space case.

PID Control - California Institute of Technology

A proportional-integral-derivative controller (PID controller or three-term controller) is a control loop mechanism employing feedback that is widely used in industrial control systems and a variety of other applications requiring continuously modulated control. A PID controller continuously calculates an error value

2. State-Space After a little algebra, the linearized system equations equations can also be represented in state-space form: The C matrix is 2 by 4, because both the cart's position and the pendulum's position are part of the output.
